

Name: \_\_\_\_\_

Date: \_\_\_\_\_

Period: \_\_\_\_\_

## SL IB Chem 1 Periodic Trends - Guided Notes

### Slide 3: Group numbers - IUPAC

### Slide 4: Periods - rows in the PT

- Period number (n) is also the number of energy levels occupied by \_\_\_\_\_.
- Be careful with the \_\_\_\_\_ metals (block d).

### Slide 5: Group 1 – The alkali metals

### Slide 6: Group 17 – The halogens

### Slide 7: Group 18 – The Noble gases

### Slide 8: The transition metals

### Slide 9: Lanthanoids

### Slide 10: Actinoids

### Slide 11: Actinoids

### Slide 12: Periodicity

- The periodic table is arranged to show that properties of elements repeat \_\_\_\_\_.
- These include:
  - \_\_\_\_\_ nuclear charge
  - Atomic radius
  - Ionic radius
  - Ionization energy
  - Electron affinity
  - Electronegativity

### Slide 13: Trends in Effective Nuclear Charge

- **Nuclear charge** is \_\_\_\_\_ by number of protons in the nucleus.
- **Effective nuclear charge** is the force \_\_\_\_\_ by outer electrons from the nucleus. It is less than force experienced by inner electrons due to **shielding**.

- \_\_\_\_\_ across a period
- \_\_\_\_\_ down a group
- \_\_\_\_\_ across a period
- Stays the same down a group

#### Slide 14: Trends in Atomic Radius

- \_\_\_\_\_ the trends in atomic radius.
- \_\_\_\_\_ why you think this is the case.
- Think about what \_\_\_\_\_ the sizes of atoms.

#### Slide 15: Trends in Atomic Radius

- \_\_\_\_\_, atomic radius decreases across a period, because...
- more \_\_\_\_\_ but all being added to the same shell → so shielding does not change.
- more protons in the nucleus = greater nuclear charge, so stronger \_\_\_\_\_ attraction pulling electrons towards the nucleus.

#### Slide 17: Trends in Ionic Radius

- \_\_\_\_\_ **ions** smaller than parent atoms due to removal of e<sup>-</sup> from the outer shell.
- \_\_\_\_\_ **ions** larger than parent atoms due to addition of e<sup>-</sup> to the outer shell.
- Ionic radii \_\_\_\_\_ from groups 1 to 14 for cations and groups 14 to 17 for anions due to decrease in nuclear charge.

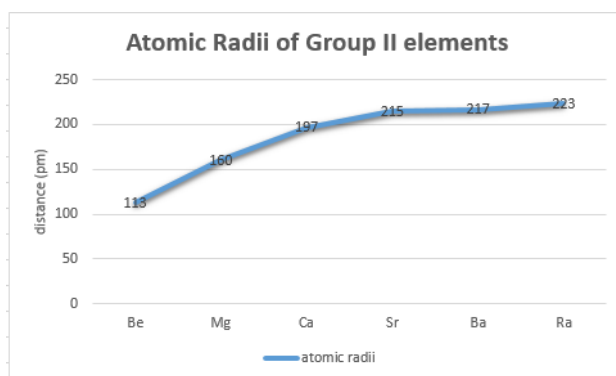

#### Slide 18: Ionisation Energy

- What is ionisation energy? The energy to remove a mole of electrons from a mole of gaseous atoms.
- What is the first ionisation energy? Removing the first (or 1 electron)

## Slide 19: Period 3 - First Ionisation Energy

- What is ionisation energy?
- What is the first ionisation energy?
- Write the 1st IE for sodium.
- Trend across period 3 = GENERAL increase.
- Variation only needed for HL.

## Slide 20: Atomic radius

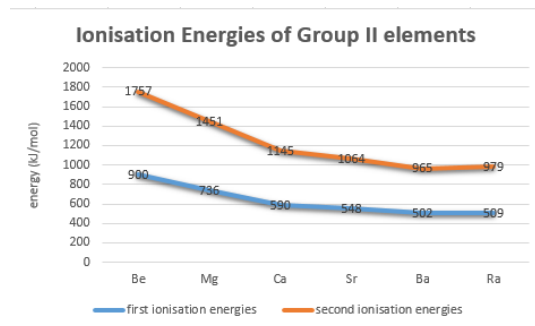

## Slide 21: Ion radius vs atom radius

- An ion has a different radius to an atom. Look at chlorine as an example. Compare the subatomic particles of Cl and Cl<sup>-</sup>. Which would be smaller and why?

1A		2A		3A	
Li 1.52	Li <sup>+</sup> 0.60	Be 1.11	Be <sup>2+</sup> 0.31		
Na 1.86	Na <sup>+</sup> 0.95	Mg 1.60	Mg <sup>2+</sup> 0.65	Al 1.43	Al <sup>3+</sup> 0.50
K 2.31	K <sup>+</sup> 1.33	Ca 1.97	Ca <sup>2+</sup> 0.99	Ga 1.22	Ga <sup>3+</sup> 0.62
Rb 2.44	Rb <sup>+</sup> 1.48	Sr 2.15	Sr <sup>2+</sup> 1.13	In 1.62	In <sup>3+</sup> 0.81

## Slide 22: Ionisation energies

- **IE decrease down group 2. Why?**
- More shielding.
- Larger atomic radius.
- Therefore more reactive (less energy needed to remove electrons in order to gain full valence shell).

## Slide 23: Electron affinity

- The first electron affinity is the energy released when 1 mole of gaseous atoms each acquire an electron to form 1 mole of gaseous 1- ions.
- This is more easily seen in symbol terms.
- $X_{(g)} + e^{-} \rightarrow X^{-}_{(g)}$
- First electron affinities have negative values. For example, the first electron affinity of chlorine is  $-349 \text{ kJ mol}^{-1}$ . By convention, the negative sign shows a release of energy.
- Write equations for the 1st and 2nd electron affinities for Na and Cl.

## Slide 24: Electronegativity

- Electronegativity is the power of an atom to pull electrons towards itself

(often in a covalent bond).

- E.g. chlorine attracts electrons more than sodium, even though they have the same number of shells. Why might this be?
- What would be the most electronegative element and why? What would be the least electronegative element and why?

### Slide 25: Pauling Scale

- IN YOUR DATA BOOKS!

### Slide 26: Trends in electronegativity

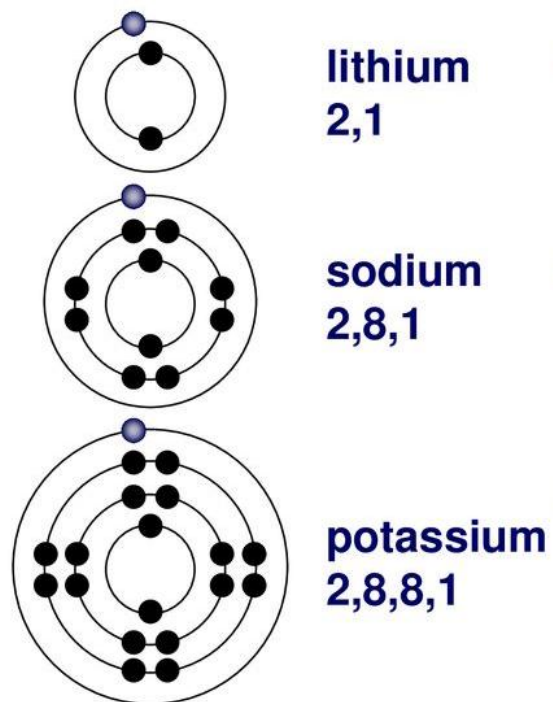

### Slide 27: Metallic character

- Metallic character is the name given to the set of chemical \_\_\_\_\_ associated with elements that are metals. These **chemical properties** result from how readily metals lose their electrons to form cations (positively charged ions).
- **Physical properties** associated with metallic character include metallic luster, shiny appearance, high density, high thermal \_\_\_\_\_, and high electrical conductivity. Most metals are malleable and ductile and can be deformed without breaking.

### Slide 28: Copy and complete the table

### Slide 31: Alkali metals and water

### Slide 32: Alkali metals and halogens

All alkali metals react violently when heated with halogens to form alkali halides. For example,

**lithium + chlorine → lithium chloride**

**sodium + chlorine → sodium chloride**

**lithium**  
**2,1**

**sodium**  
**2,8,1**

**potassium**  
**2,8,8,1**

Slide 33: Appearances of the Halogens
